

Machine Learning

Session 21 - T

Ensemble Learning and Hyperparameter Optimization

Ciência de Dados Aplicada 2023/2024

Ensemble Learning

 Ensemble learning aims to build high-performance predictive models by combining simpler base models;

- There are different types of ensemble learning. The most common ones are:
 - Bagging (already covered in the Random Forests session!)
 - Boosting (already covered in the Random Forests session!)
 - Stacking
 - Voting

Bagging Recap

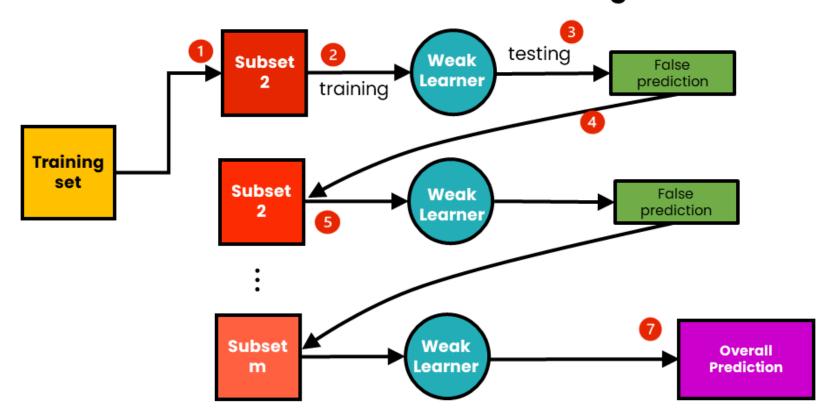

https://www.datacamp.com/tutorial/what-bagging-in-machine-learning-a-guide-with-examples

Boosting Recap

The Process of Boosting

https://medium.com/@brijesh_soni/understanding-boosting-in-machine-learning-a-comprehensive-guide-bdeaa1167a6

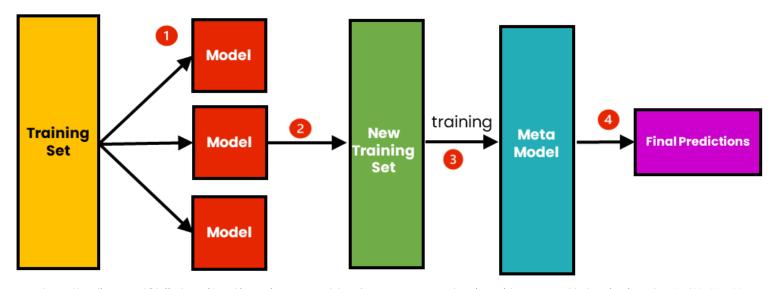

Stacking

- The algorithm of stacking is:
 - Train N models on the training data;
 - Train a meta model on the predictions of the ensemble of models.

The Process of Stacking

https://medium.com/@brijesh_soni/stacking-to-improve-model-performance-a-comprehensive-guide-on-ensemble-learning-in-python-9ed53c93ce28

Bagging vs Boosting vs Stacking

	Bagging	Boosting	Stacking
Purpose	Reduce Variance	Reduce Bias	Improve Accuracy
Base Learner Types	Homogeneous	Homogeneous	Heterogeneous
Base Learner Training	Parallel	Sequential	Meta Model
Aggregation	Max Voting, Averaging	Weighted Averaging	Weighted Averaging

https://www.analyticsvidhya.com/blog/2023/01/ensemble-learning-methods-bagging-boosting-and-stacking/

Voting Ensemble

- Similar to Bagging without the bootstraping;
- Uses heterogeneous models;
- Majory voting for classification averaging / weighted average for regression.

Voting Classifier

Hard vs Soft Voting

Hyperparameter Optimization

Also called metaparameter optimization;

Also called hyperparameter tunig;

Any system that chooses hyperparameters automatically;

 What is the difference between the model parameters and hyperparameters?

Hyperparameter Optimization

- What is a hyperparameter?
 - Parameters that the user need to specify in order to run a machine learning algorithm;
- What are some hyperparameters for the following models?
 - K-nearest-neighbot (kNN);
 - Decision Tree;
 - Neural Network.

Grid Search

Define some grid of parameters you want to try;

- Try all the parameter values in the grid:
 - By running the whole system for each combination of parameters;
- Then choose the combination with the best results;

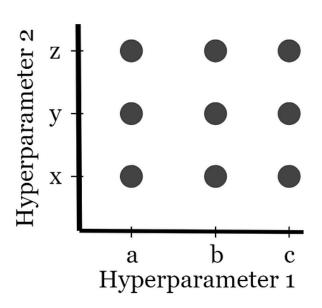

It is essentially a brute force method.

Grid Search

Pseudocode

Hyperparameter_One = [a, b, c]

Hyperparameter_Two = [x, y, z]

Grid Search - Disadvantages

- As the number of parameters increases, the cost of grid search increases exponentially!
 - Why?
- Still need some way to choose the grid properly:
 - This can be as hard as the original hyperparameter optimization;

Can't take advantage of any insight you have about the system!

Randomized Search

 This is similar to grid search, but instead of trying all hyperparameter combinations try some random combinations;

- This solves the curse of dimentionality:
 - The number of trials do not grow exponetially as the number odf dimentions increases;
- Problem: we do not necessarily get anywhere near the optimal hyperparameters in a small sample.

Random Search

Pseudocode

Hyperparameter_One = random.num(range)
Hyperparameter Two = random.num(range)

Hyperparameter 1

 Bayesian approaches, in contrast to random or grid search, keep track of past evaluation results;

- They form a probabilistic model mapping hyperparameters to a probability of a score on the objective function:
 - P(score | hyperparameters)
- This is called a "surrogate" for the objective function. This surrogate is **much easier to optimize** than the objective function;

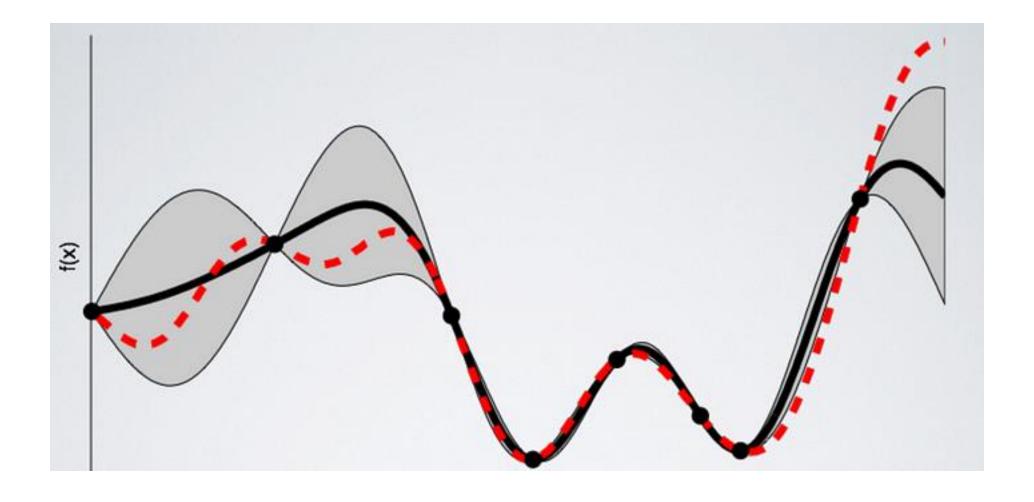

- Bayesian optimization steps:
 - 1. Build a surrogate probability model of the objective function
 - 2. Find the hyperparameters that perform best on the surrogate
 - 3. Apply these hyperparameters to the true objective function
 - 4. Update the surrogate model incorporating the new results
 - 5. Repeat steps 2–4 until max iterations or time is reached
